

Moving towards a new psychiatry: targeting patient subtypes and symptom domains

an industry perspective of the current challenges

Daniel Oravetz is a patient and artist from
Hungary, living with schizophrenia.

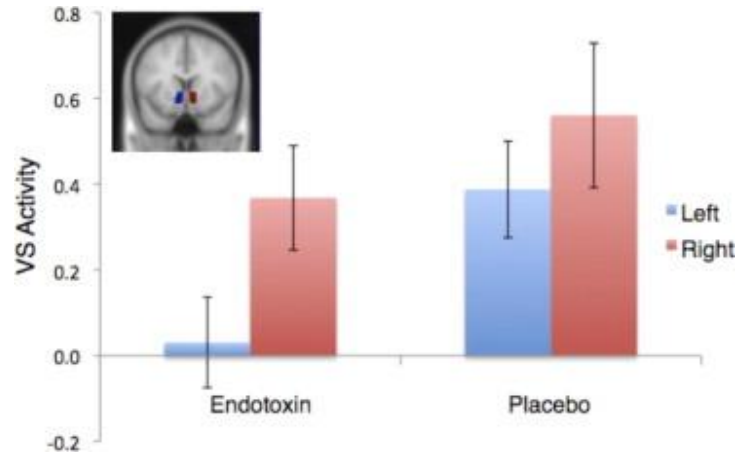

Disclosures

- Employee and shareholder of Johnson & Johnson, LLC

Peripheral immune dysregulation as a potential antidepressant target

- Patients with depression show increased levels of peripheral inflammatory markers, including TNF-alpha, IL-6 and CRP
- Preclinical evidence that drugs which suppress peripheral inflammation (anti IL-6 antibodies) are able to trigger antidepressant-like response in susceptible animals
- Clinical evidence that antibodies which suppress peripheral inflammation improve depression symptoms in subjects with elevated peripheral inflammatory markers as well as subjects with primary inflammatory conditions
- PoC study to test the hypothesis that treatment with the anti-IL-6 antibody sirukumab improves depression symptoms in patients with MDD with increased CRP levels
- Investigation of the effects of sirukumab on anhedonia using the SHAPS scale

Association between peripheral inflammation and activity in the reward circuitry

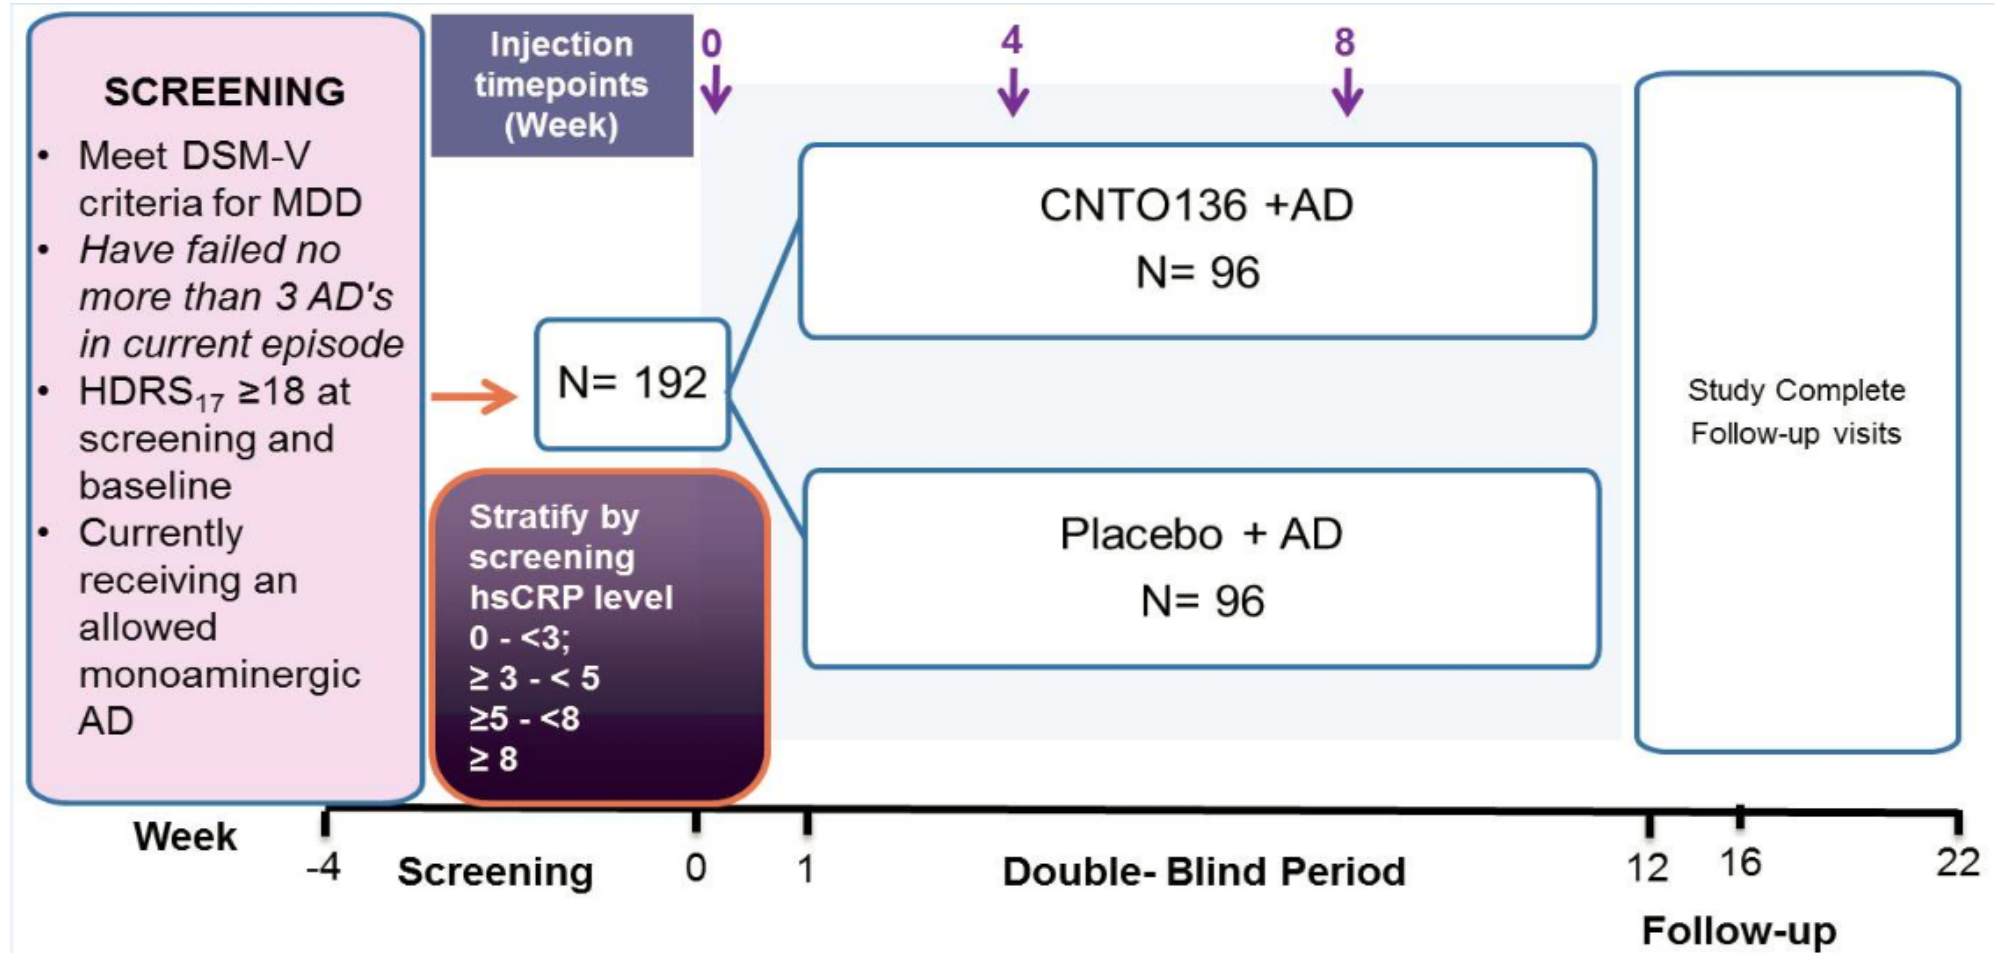

- Elevation of peripheral cytokines through LPS challenge blunts ventral striatal activity
- Decreased activity in the reward circuitry might mediate depressive symptoms post-LPS challenge

- Increased CRP correlates with decreased FC between the ventral striatum and the vmPFC
- This association mediates the relationship between CRP and anhedonia

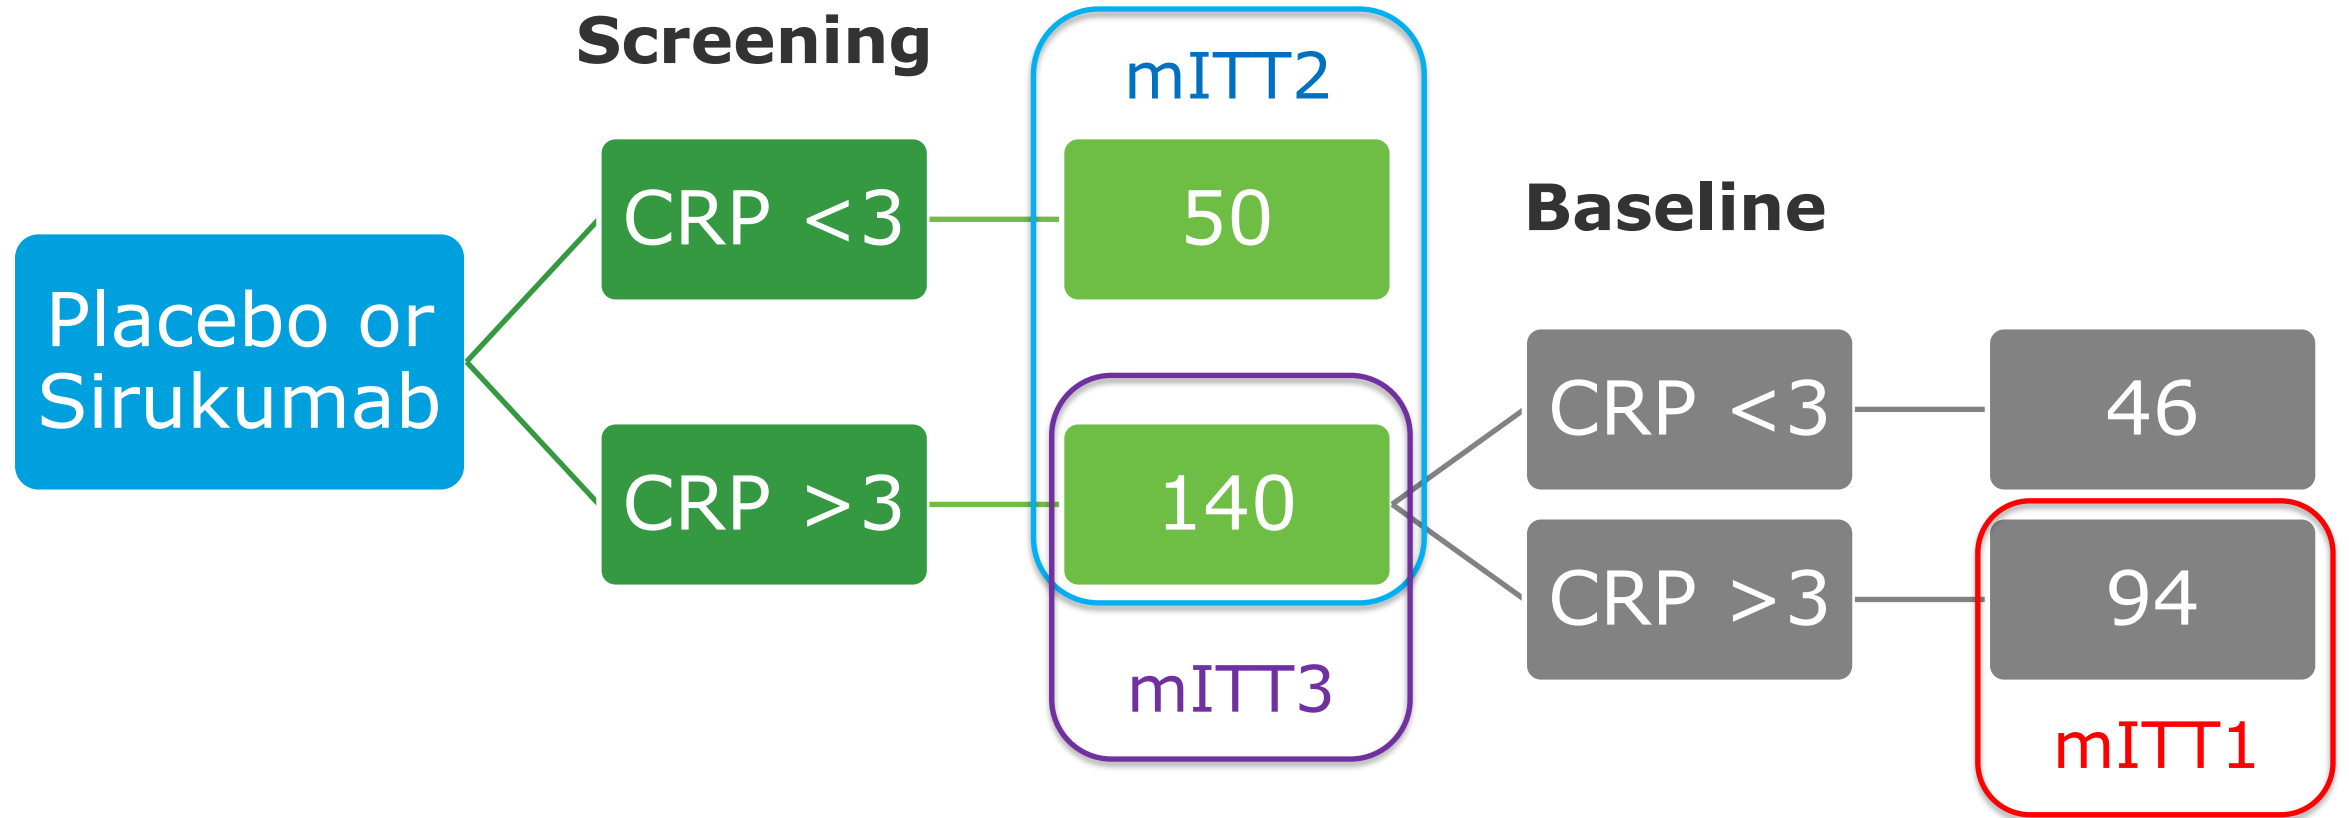

Study design

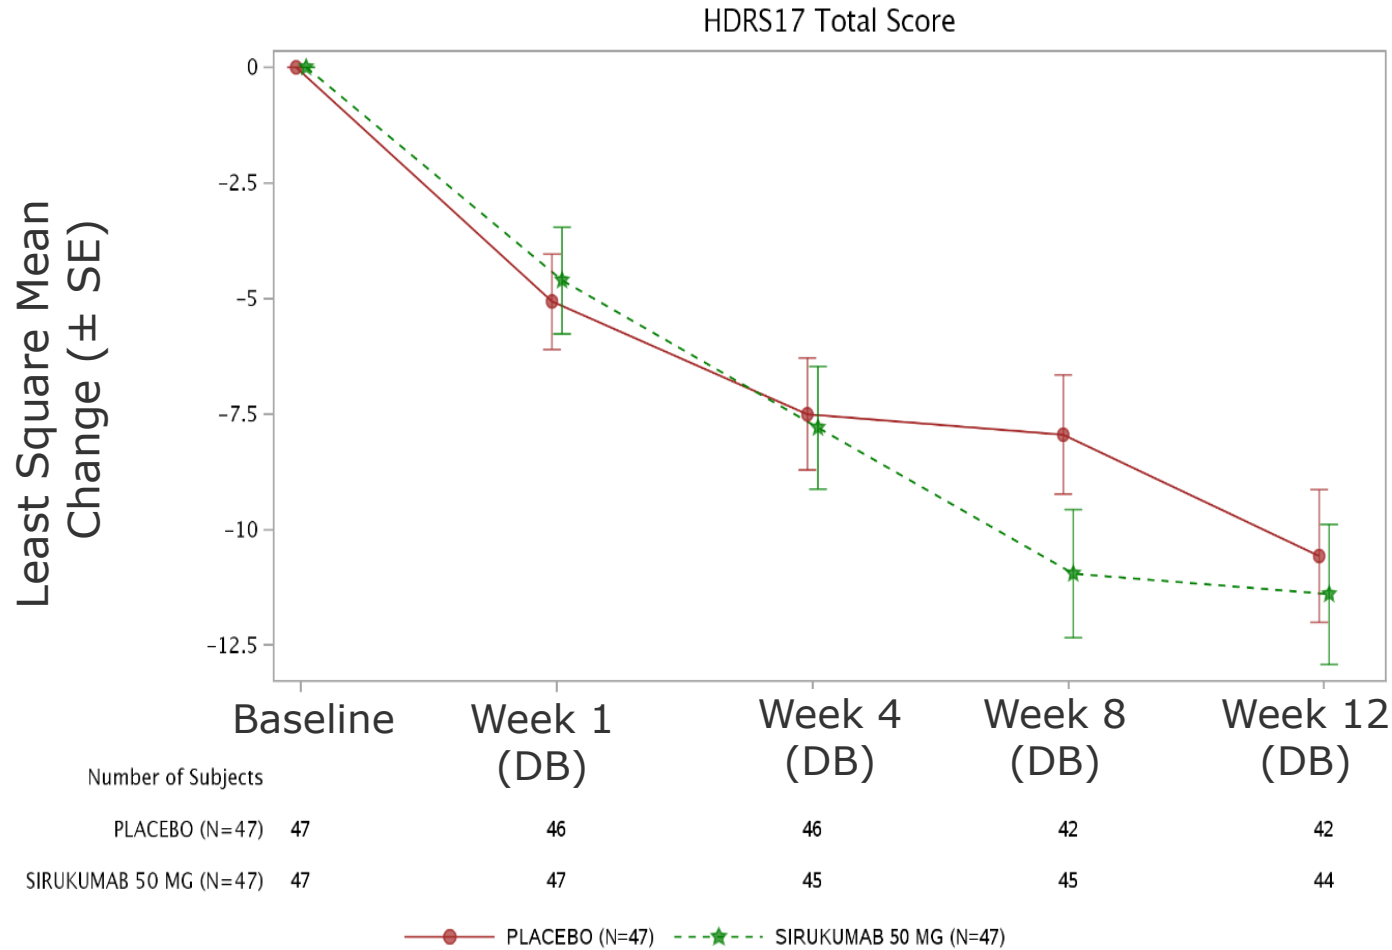

Only subjects with screening and baseline CRP ≥ 3.00 mg/L will contribute to the primary analysis

Study Subjects Info in Each Analysis Set

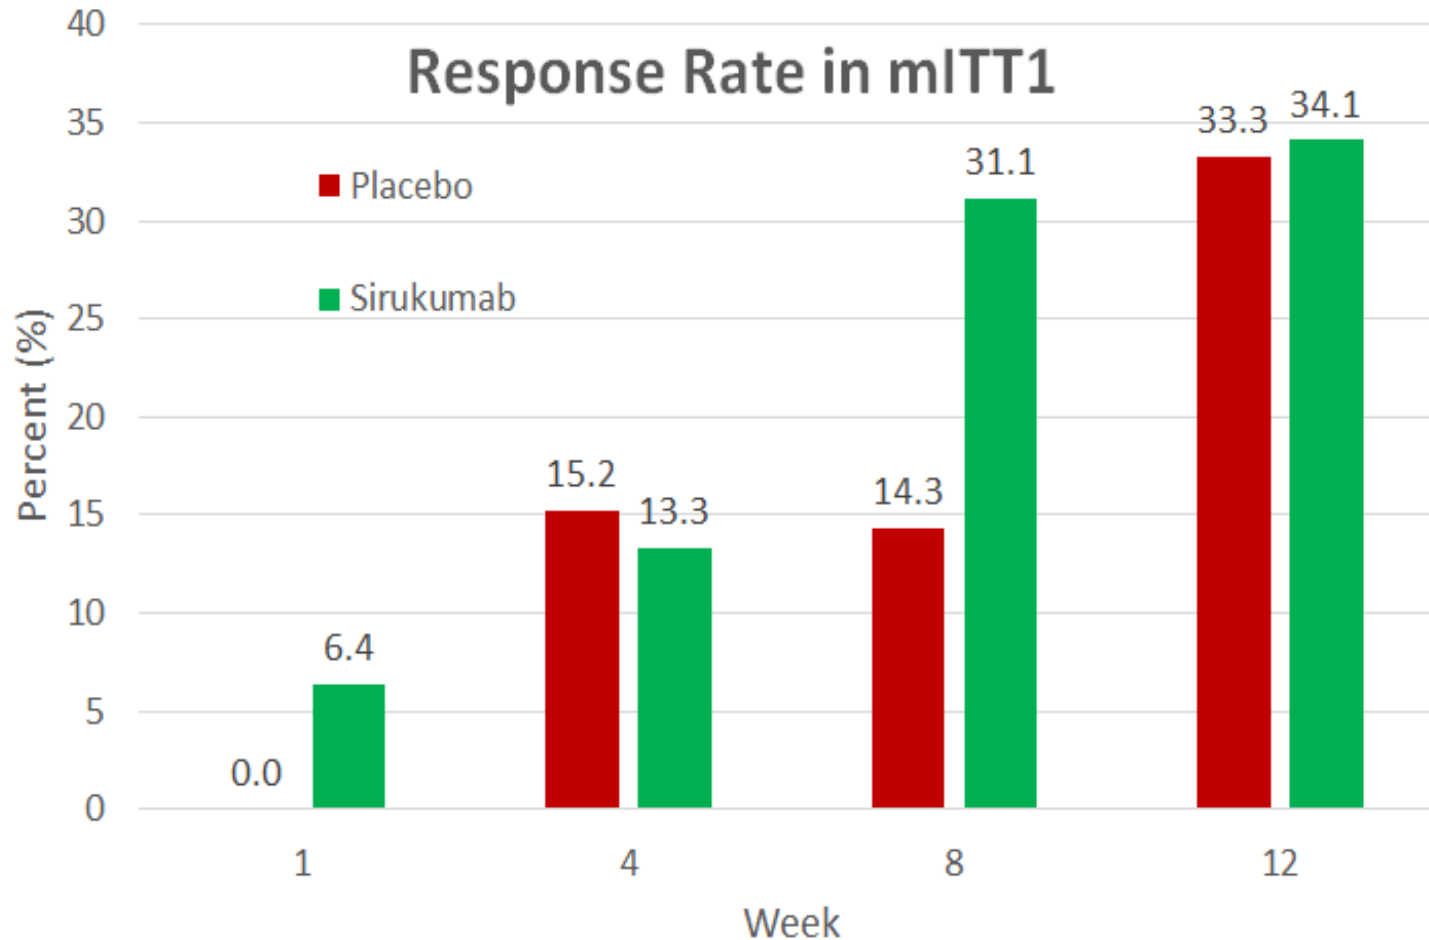

Depressed subjects showed elevation of CRP at screening: average CRP 4.2 mg/L (N=931)

HDRS-17 primary efficacy results in mITT1 population

No effect of sirukumab at Week 12 on HDRS-17 scores (independent raters) in mITT1 population

Response Rate is comparable between sirukumab and placebo at Week 12

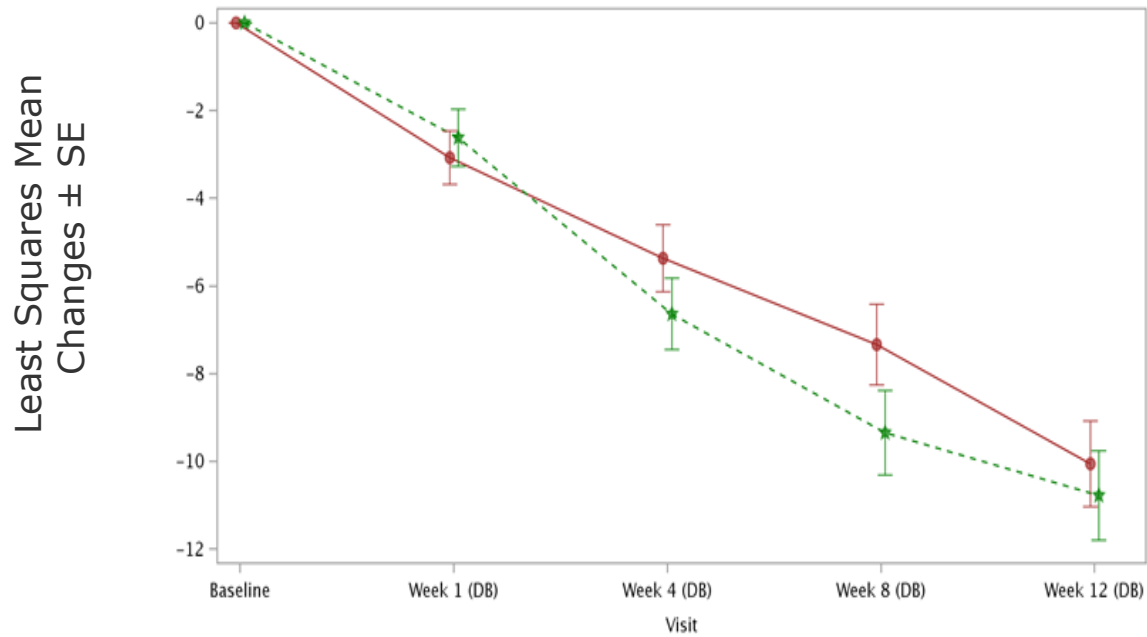

Response defined as $\geq 50\%$ improvement in HDRS-17 total score from baseline

Week 12 response rate didn't favor sirukumab over placebo

HDRS-17: Sirukumab Fails to Differentiate from Placebo at 12 weeks Regardless of Screening CRP levels

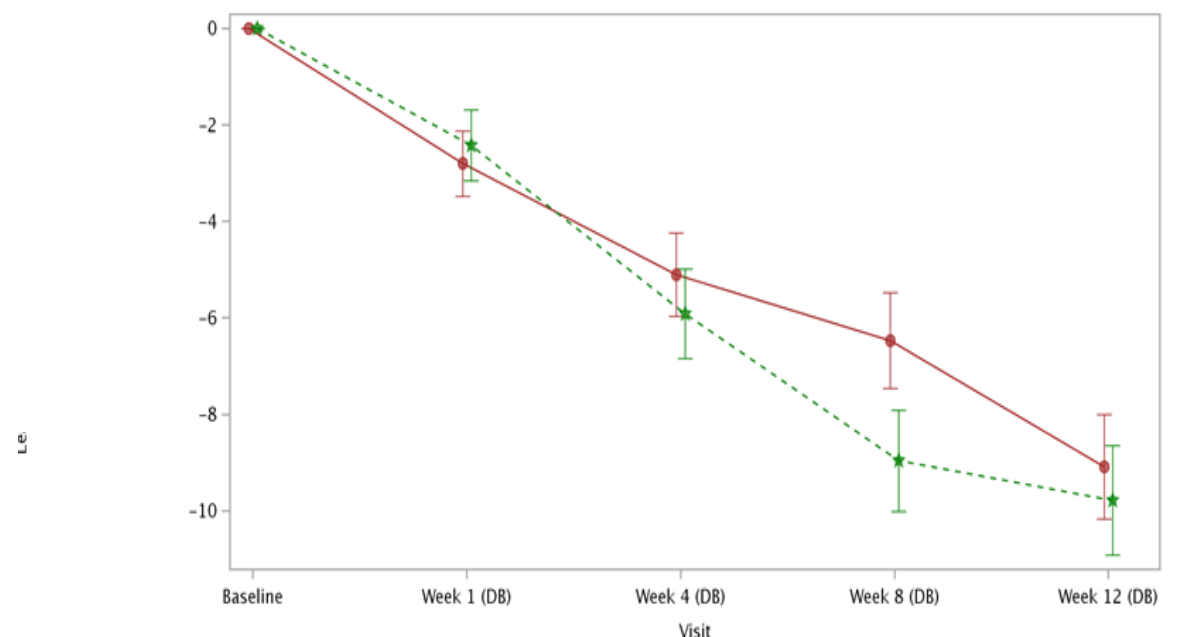

mITT2

Number of Subjects		Baseline	Week 1 (DB)	Week 4 (DB)	Week 8 (DB)	Week 12 (DB)
PLACEBO (N=98)	98	97	97	87	85	
SIRUKUMAB 50 MG (N=93)	93	93	87	84	81	

● PLACEBO (N=98)
 ★ SIRUKUMAB 50 MG (N=93)

mITT3

Number of Subjects		Baseline	Week 1 (DB)	Week 4 (DB)	Week 8 (DB)	Week 12 (DB)
PLACEBO (N=73)	73	72	72	66	64	
SIRUKUMAB 50 MG (N=67)	67	67	65	63	62	

● PLACEBO (N=73)
 ★ SIRUKUMAB 50 MG (N=67)

Sirukumab treatment is associated with decreased peripheral inflammatory biomarkers

Changes from baseline to week 12 in IL-6 (Left) and hsCRP (Right) stratified by baseline hsCRP levels

SHAPS: Sirukumab improves anhedonia symptoms in MDD subjects

Number of Patients

Placebo (N=47)	46	45	45	41	43	42	41
Sirukumab (N=47)	47	47	45	45	44	44	43

●— Placebo (N=47) ★- - Sirukumab 50 mg (N=47)

Study results summary

- Lack of efficacy using a “general” depression scale despite adequate suppression of peripheral inflammatory biomarkers
- Lack of an enrichment biomarker to identify responders
- Promising signal on an anhedonia scale
- Positive effect on anhedonia is plausible from a biological standpoint
- Previous positive studies with monoclonal antibodies used depression rating scales that emphasize anhedonia, such as the HADS

Is there a path forward for drugs which target anhedonia?

- Regulatory hurdles: showing that anti-anhedonic effects are not part of a general antidepressant effect to avoid pseudo-specificity
- Development hurdles: does a drug improve anhedonia in subjects with MDD only or improve anhedonia across different diagnosis?
- Payers hurdles: how do we show quantifiable value for anhedonia to payers?
 - What is the burden of untreated anhedonia?
- Prescribers hurdles: do they see anhedonia as an area of unmet need? How do they identify subjects with anhedonia?
