Precision medicine in 2030— seven ways to transform healthcare

Joshua C. Denny^{1,3,*} and Francis S. Collins²

Precision medicine promises improved health by accounting for individual variability in genes, environment, and lifestyle. Precision medicine will continue to transform healthcare in the coming decade as it expands in key areas: huge cohorts, artificial intelligence (AI), routine clinical genomics, phenomics and environment, and returning value across diverse populations.

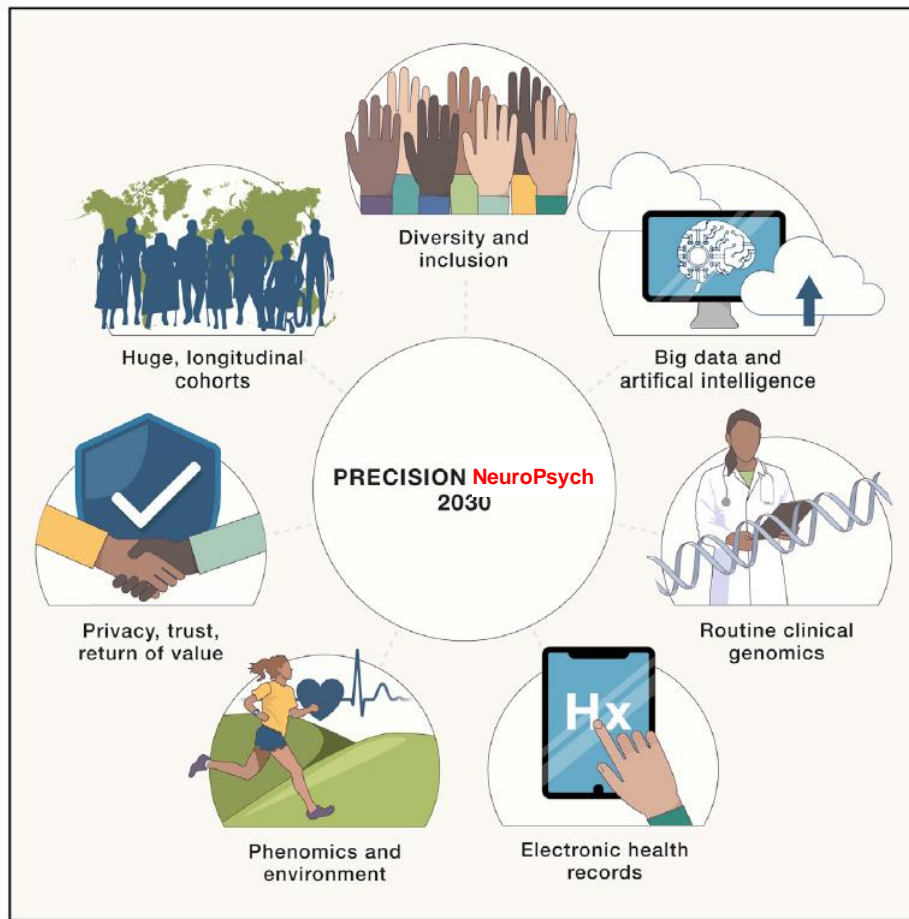

Figure 1. Seven opportunities for precision medicine by 2030

Roadmap for a precision-medicine initiative in the Nordic region

The Nordic region, comprising primarily Denmark, Estonia, Finland, Iceland, Norway and Sweden, has many of the necessary characteristics for being at the forefront of genome-based precision medicine. These include egalitarian and universal healthcare, expertly curated patient and population registries, biobanks, large population-based prospective cohorts linked to registries and biobanks, and a widely embraced sense of social responsibility that motivates public engagement in biomedical research. However, genome-based precision medicine can be achieved only through coordinated action involving all actors in the healthcare sector. Now is an opportune time to organize scientists in the Nordic region, together with other stakeholders including patient representatives, governments, pharmaceutical companies, academic institutions and funding agencies, to initiate a Nordic Precision Medicine Initiative. We present a roadmap for how this organization can be created. The Initiative should facilitate research, clinical trials and knowledge transfer to meet regional and global health challenges.

Genetic 'revolution' in neuropsychiatry

- Reduced genotyping costs – massive genotyped samples
 - Polygenic architecture
 - Multiple small effects
- «Genotyping your DNA is cheaper than parking at the hospital»

Case-control (GWAS)

Flickr

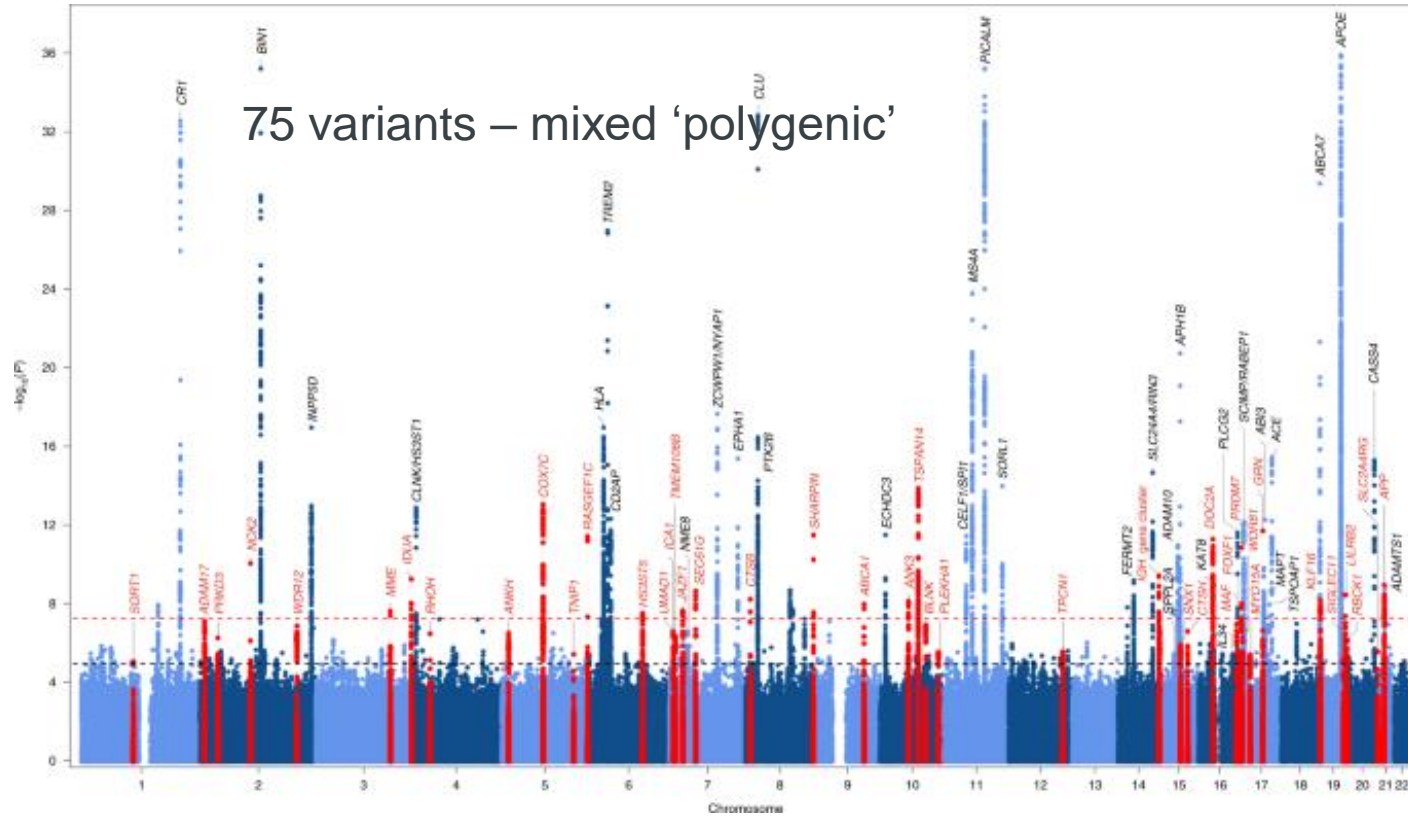

2022: schizophrenia - 270 loci

2024: Bipolar disorder - 298 loci

2022: Alzheimer's disease

Polygenic score

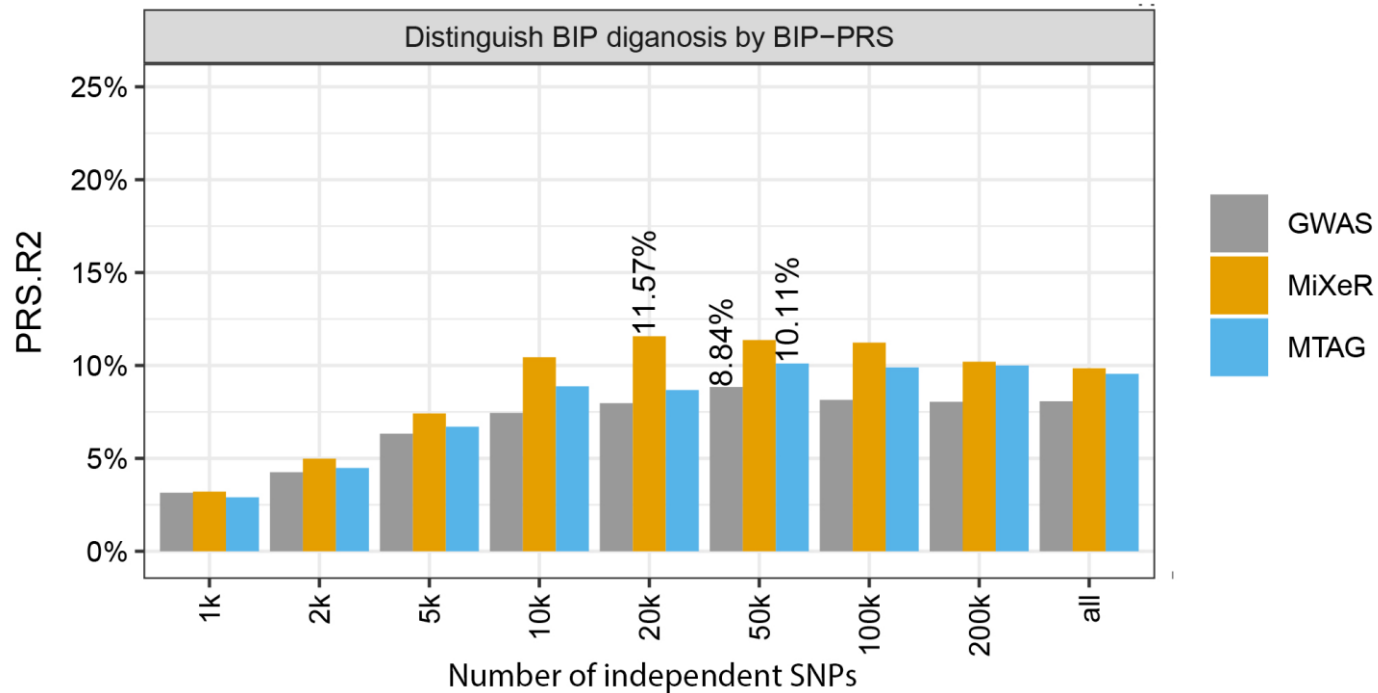

- Cumulative effect of all small genetic variants
 - Genotype individual – calculate risk of disease

Polygenic score

Polygenic prediction bipolar disorder

Genetics and drug response – «Stratification»

- Large variation in treatment response
- Large variation in adverse effects
- Trial-and-error approach

Can genetic variants predict response/adverse effects of psychopharmacology agents?

- precision medicine in psychiatry

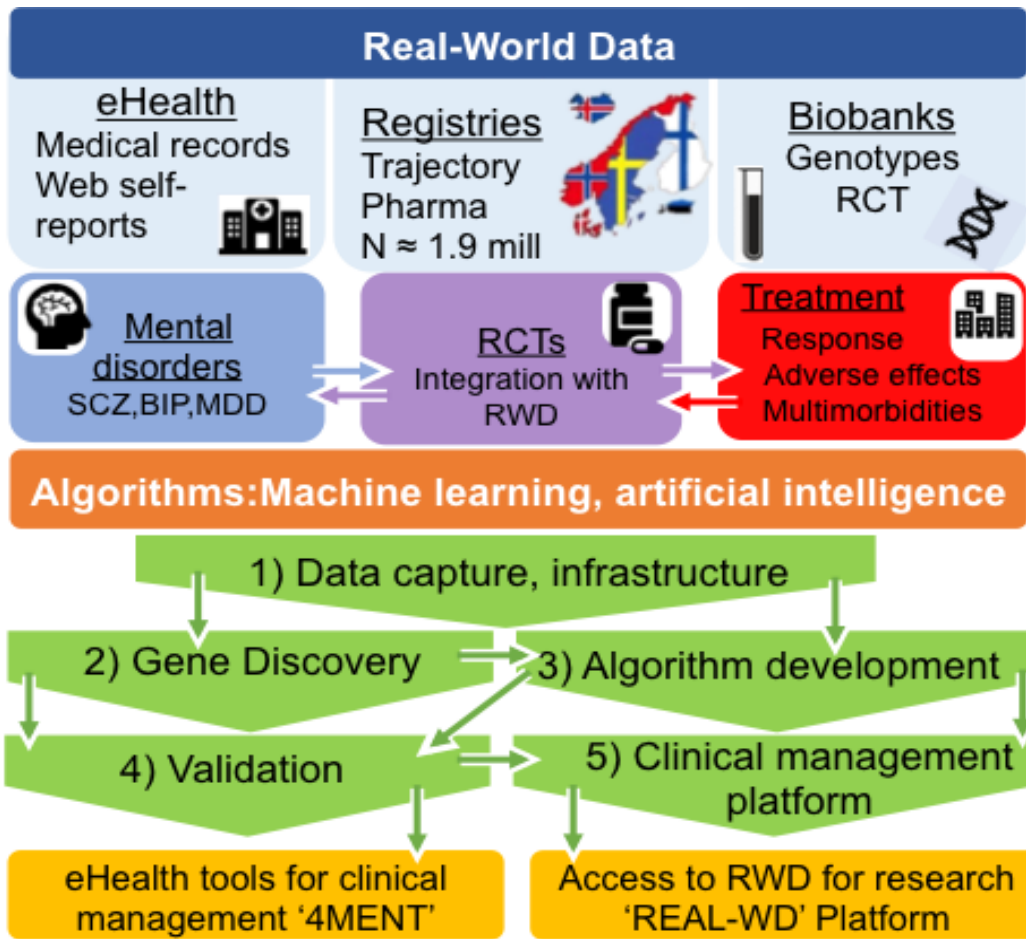

- Need large training data (GWAS)

Fix the process that led to Alzheimer's drug fiasco

Reforms to accelerated approval should focus on securing reliable information in the present and clinical evidence for the future

[Jason Karlawish](#) 

The morning of 7 June 2021 was a shock. The US Food and Drug Administration approved aducanumab, the first treatment targeting β -amyloid, a protein associated with Alzheimer's disease.

Although some celebrated the approval of the first Alzheimer's drug in nearly a century, others were aghast at the lack of demonstrated efficacy: ten members of a panel of experts assembled by the FDA had voted against approving it, with the one remaining 'uncertain'. Three quit in protest when the drug was approved.

NEWS | 07 January 2023 | Correction [10 January 2023](#)

FDA approves Alzheimer's drug lecanemab amid safety concerns

Reports of deaths potentially linked to the treatment have cast a shadow on what many hail as a landmark approval.

Real-world data quality and access?

- Standardization initiatives real-world data (Nordic registries, UK Biobank, All-of-Us and many others)
- Validation in RCT data (collaboration with industry partners)
 - Cross industry opportunities?
- Data access – sensitive data
 - Tryggve – federated data analytical pipeline
 - Developing academia-industry infrastructures, e.g. FinnGen
- FDA/EMA real-world data for drug approvals?
- Ethical challenges with precision psychiatry
